

## Normalization:

One important thing about BN algorithm is that it normalize the input right **before** activation:

$$\begin{aligned} y^l &\leftarrow \mathcal{BN}(W^{l-1,l}u^{l-1}) \\ u^l &= g(y^l) \end{aligned}$$

$g(u)$  is activation function. It can be *sigmoid*, *ReLU* etc.  $W^{l-1,l}$  is the weights linking layers  $l-1, l$ ,  $u^l$  is the input to layer  $l$ . To summarize the normalization in B.N.:

$$\begin{aligned} x^l &= W^{l-1,l}u^{l-1} \\ \hat{x}^l &= \frac{x^l - \mu_B^l}{\sqrt{\sigma_B^{2,l}}} \\ y^l &= \gamma^l \hat{x}^l + \beta^l \\ u^l &= g(y^l) \end{aligned}$$

## Back-Propagation:

Cost function  $\mathcal{C}(\gamma, \beta, W, \hat{\theta}, \psi, \phi)$  is a function of hyper parameter  $\hat{\theta}$ , training parameter  $\{\gamma, \beta, W\}$ , input  $\psi$  and label  $\phi$ . The whole business is centered at minimizing this beast. Define growth rate at layer  $l$ :  $\Delta_s^l \equiv \frac{\partial \mathcal{C}}{\partial y_s^l}$ . Here  $y_s^l$  is the linear combination of sample  $s$  that waits to be activated. Using chain rule, BP for BN can be derived as below. It differs with the baseline BP slightly.

$$\begin{aligned} \frac{\partial \mathcal{C}}{\partial W^{l-1,l}} &= \sum_s \frac{\partial \mathcal{C}}{\partial y_s^l} \frac{\partial y_s^l}{\partial W^{l-1,l}} \equiv \sum_s \Delta_s^l \frac{\partial y_s^l}{\partial W^{l-1,l}} \\ \frac{\partial y_s^l}{\partial W^{l-1,l}} &= \frac{\gamma^l}{\sqrt{\sigma_B^{2,l}}} \left[ u_s^{l-1} - \langle u^{l-1} \rangle - \hat{x}^l \langle u^{l-1} \hat{x}^l \rangle \right] \\ \Delta_s^l &= \frac{\gamma^{l+1}}{\sqrt{\sigma_B^{2,l+1}}} W^{l,l+1} g'(y_s^l) \left[ \Delta_s^{l+1} - \langle \Delta^{l+1} \rangle - \hat{x}_s^{l+1} \langle \Delta^{l+1} \hat{x}^{l+1} \rangle \right] \\ \frac{\partial \mathcal{C}}{\partial \beta^l} &= \sum_s \frac{\partial \mathcal{C}}{\partial y_s^l} \\ \frac{\partial \mathcal{C}}{\partial \gamma^l} &= \sum_s \frac{\partial \mathcal{C}}{\partial y_s^l} \hat{x}_s^l \end{aligned}$$

$\langle \dots \rangle$  is the sample average.  $s$  is the label of sample in a mini-batch.  $l$  labels layer.  $g'(x)$  is the derivative of activation function. At the boundary:

$$\Delta_s^L = \frac{\partial \mathcal{C}}{\partial u_s^L} g'(y_s^L)$$

$L$  labels the last layer in network.
